Today: Bits, Bytes, and Integers

Representations in memory, pointers, strings

Byte-Oriented Memory Organization

Programs refer to data by address

- Conceptually, envision it as a very large array of bytes
 - In reality, it's not, but can think of it that way
- An address is like an index into that array
 - and, a pointer variable stores an address

■ Note: system provides private address spaces to each "process"

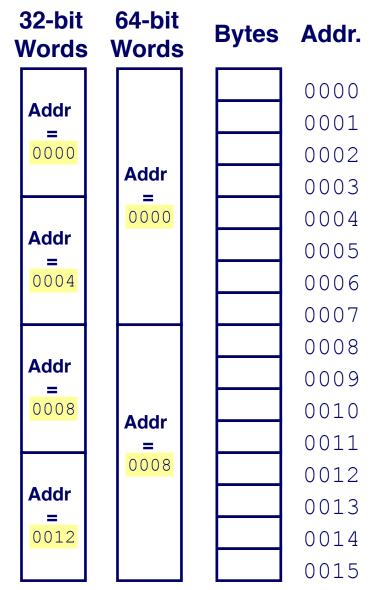

- Think of a process as a program being executed
- So, a program can clobber its own data, but not that of others

Machine Words

- Any given computer has a "Word Size"
 - Nominal size of integer-valued data
 - and of addresses
 - Until recently, most machines used 32 bits (4 bytes) as word size
 - Limits addresses to 4GB (2³² bytes)
 - Increasingly, machines have 64-bit word size
 - Potentially, could have 18 EB (exabytes) of addressable memory
 - That's 18.4 X 10¹⁸
 - Current machines only use lower 48 bits.
 - Machines still support multiple data formats
 - Fractions or multiples of word size
 - Always integral number of bytes

Word-Oriented Memory Organization

- Addresses Specify Byte Locations
 - Address of first byte in word
 - Addresses of successive words differ by 4 (32-bit) or 8 (64-bit)

Example Data Representations

C Data Type	Typical 32-bit	Typical 64-bit	x86-64	
char	1	1	1	
short	2	2	2	
int	4	4	4	
long	4	8	8	
float	4	4	4	
double	8	8	8	
long double	-	-	10/16	
pointer	4	8	8	

Byte Ordering

- So, how are the bytes within a multi-byte word ordered in memory?
- Conventions
 - Big Endian: Sun, PPC Mac, Internet
 - Least significant byte has highest address
 - Little Endian: x86, ARM processors running Android, iOS, and Windows

& Litherawan Slive nove brugt

Least significant byte has lowest address

Byte Ordering Example

Example

- Variable x has 4-byte value of 0x01234567
- Address given by &x is 0x100

Big Endian		0×100	0×101	0x102	0x103	
		01	23	45	67	
Little Endia	ın	0x100	0x101	0x102	0x103	
		67	45	23	01	

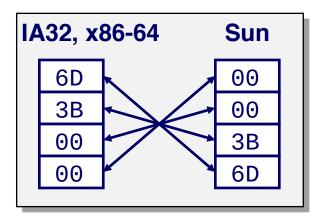

Representing Integers

Decimal: 15213

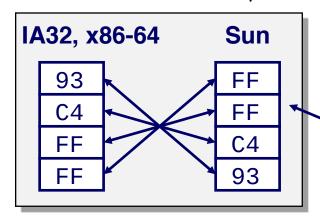

Binary: 0011 1011 0110 1101

Hex: 3 B 6 D

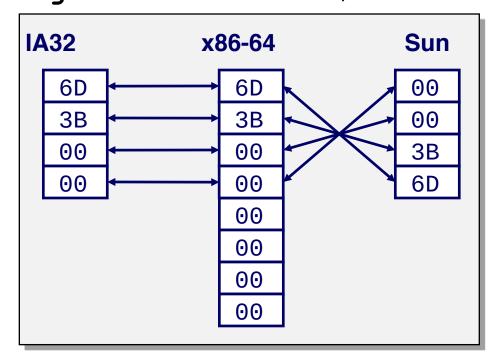

int A = 15213;

int B = -15213;

long int C = 15213;

Two's complement representation

Examining Data Representations

- Code to Print Byte Representation of Data
 - Casting pointer to unsigned char * allows treatment as a byte array

```
void show_bytes(unsigned char* start, size_t len) {
   size_t i;
   for (i = 0; i < len; i++)
      printf("%p\t0x%.2x\n",start+i, start[i]);
   printf("\n");
}</pre>
```

Printf directives:

%p: Print pointer

%x: Print Hexadecimal

show_bytes Execution Example

```
int a = 15213;
printf("int a = 15213;\n");
show_bytes((pointer) &a, sizeof(int));
```

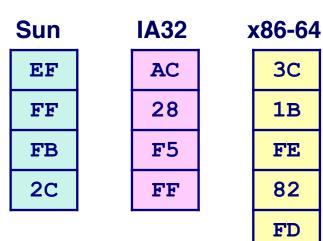

Result (Linux x86-64):

```
int a = 15213;
0x7fffb7f71dbc 6d
0x7fffb7f71dbd 3b
0x7fffb7f71dbe 00
0x7fffb7f71dbf 00
```

Representing Pointers

int
$$B = -15213;$$

int *P = &B

3C

1B

FE

82

FD

7F

00

00

Different compilers & machines assign different locations to objects.

Even get different results each time run program.

Representing Strings

char S[6] = "18213";

Strings in C

- Represented by array of characters
- Each character encoded in ASCII format
 - Standard 7-bit encoding of character set
 - Character "0" has code 0x30
 - − Digit i has code 0x30+i
- String should be null-terminated
 - Final character = 0

Compatibility

Byte ordering not an issue
